

# Python102

Python for Data Science Bootcamp

## **(6.3) Machine Learning Basics with Python Part 3**

*AIAT Academy*

# Machine Learning Basics

- Machine Learning Basic Part 1
  - Machine Learning with Python using Scikit Learn
  - Linear Regression
  - Logistic Regression
- Machine Learning Basic Part 2
  - Support Vector Machine (SVM)
  - K means Clustering
- **Machine Learning Basic Part 3**
  - **Natural Language Processing (NLP)**
  - **Neural Network and Deep Learning**

# Natural Language Processing (NLP)

# Natural Language Processing (NLP)

- Imagine you work for Google News and you want to group news articles by topic
- Or you work for a legal firm and you need to filter thousands of document pages to find relevant ones
- NLP can help you

# Natural Language Processing (NLP)

- To do so, we want to
  - Compile documents
  - Featurize them
  - Compare their features

# Natural Language Processing (NLP)

- To do so, we want to
  - Compile documents
  - Extract features from them
  - Compare their features

# Natural Language Processing (Simple Example)

- You have two short documents
  - "Blue House"
  - "Red House"
- Extract features on word count
  - "Blue House": (Blue, House, Red): (1, 1, 0)
  - "Red House": (Blue, House, Red): (0, 1, 1)

# Natural Language Processing (Simple Example)

- The documents represent as a **vector** or word count is called

## "Bag of Words"

- "Blue House": (Blue, House, Red): (1, 1, 0)
- "Red House": (Blue, House, Red): (0, 1, 1)
- In principle, you can use cosine similarity on the vectors to calculate similarity between documents

$$\text{similarity}(A,B) = \frac{A \cdot B}{\|A\| \times \|B\|} = \frac{\sum_{i=1}^n A_i \times B_i}{\sqrt{\sum_{i=1}^n A_i^2} \times \sqrt{\sum_{i=1}^n B_i^2}}$$

# Natural Language Processing (Simple Example)

- We can improve on Bag of Words by adjusting word counts based on their frequency in corpus (the group of all documents)
- We can use TF-IDF (Term Frequency – Inverse Document Frequency)
  - Term Frequency: Importance of the term (word) within that document
    - $TF(d, t) = \text{Number of occurrences of term } t \text{ in document } d$
  - Inverse Document Frequency: Importance of the term in the corpus
    - $IDF(t) = \log(D/t)$
    - where  $D$  = total number of documents and  $t$  = number of documents with the term

# Natural Language Processing (Simple Example)

- Mathematically , TD-IDF is expressed:

$$w_{x,y} = tf_{x,y} \times \log \left( \frac{N}{df_x} \right)$$

**TF-IDF**

Term  $x$  within document  $y$

$tf_{x,y}$  = frequency of  $x$  in  $y$

$df_x$  = number of documents containing  $x$

$N$  = total number of documents

# Natural Language Processing with Python

- To start with Natural Language Processing on Python, we will need to download a library
- Go to your terminal or command line and use:

```
conda install nltk
```

or

```
pip install nltk
```

# Natural Language Processing (NLP)

## *Colab*

# Neural Networks

# Neural Networks

- Neural networks are modelled after biological neural networks and attempt to allow computers to learn in similar manner to humans  
**(reinforcement learning)**
- Use cases
  - Pattern Recognition
  - Time Series Prediction
  - Signal Processing
  - Anomaly Detection
  - Control

# Neural Networks

- Neural networks are modelled after biological neural networks and attempt to allow computers to learn in similar manner to humans  
**(reinforcement learning)**
- Use cases
  - Pattern Recognition
  - Time Series Prediction
  - Signal Processing
  - Anomaly Detection
  - Control

# Neural Networks

- The human brain has interconnected neurons with dendrites that receive inputs, and then based on those inputs, produce an electronical signal output through the axon

# Neural Networks

- There are problems that are **difficult for humans but easy for computers**
  - Calculating large arithmetic problems
- Then there are problems **easy for humans but difficult for computers**
  - Recognizing a picture of a person from the side
- **Neural Networks** attempt to solve problems that would normally be easy for humans but hard for computers

# Neural Networks (Perceptron)

- **Perceptron** in Simplest Neural Network

- A perceptron consists of one or more input, a processor, and a single output
- A perceptron follows the "feed-forward" model, meaning inputs are sent into the neuron, are processed, and result in an output

# Neural Networks (Perceptron)

- A perceptron process follows 4 mains steps
  - Receive inputs
  - Weight inputs
  - Sum inputs
  - Generate output

# Neural Networks (Perceptron)

- Let's say we have a perceptron with two inputs
  - **Input 0:  $x_1 = 12$**
  - **Input 1:  $x_2 = 4$**

# Neural Networks (Perceptron)

- Each input that is sent into the neuron must first be **weighted**
  - Multiplied by some value (often a number between -1 and 1)

# Neural Networks (Perceptron)

- When creating a perceptron, we will typically begin by assigning random weights
  - **Weight 0: 0.5**
  - **Weight 1: -1**

# Neural Networks (Perceptron)

- We take each input and multiply it by its weight
  - **Input 0 \* Weight 0:  $0.5 \Rightarrow 12 * 0.5 = 6$**
  - **Input 1 \* Weight 1:  $-1 \Rightarrow 4 * -1 = -4$**

# Neural Networks (Perceptron)

- The outputs of a perceptron is generated by passing that sum through an activation function
- In the case of a simple binary output, the activity function is what tells the perceptron whether to "fire" or not

# Neural Networks (Perceptron)

- Many activation functions to choose from (Logistic, Trigonometric, Step, etc.)
- Let's make the activation function the sign of the sum
- In other words, if the sum gives a positive number
  - the outputs is 1;
  - if it is negative, the outputs is -1

# Neural Networks (Perceptron)

- However, one more thing to consider is **Bias**
- If both inputs were equal to zero, then any sum no matter what multiplicative weight would also be zero (no generated output)
- To avoid this problems
  - Add third input known as a **bias** input with a value of 1 (this avoids the zero issues)

# Neural Networks (Perceptron)

- To train the perceptron we use the following steps
  - Provide the perceptron with inputs for which there is a known answer
  - Ask the perceptron to guess an answer
  - Compute the error (How far off from the correct answer?)
  - Adjust all the weights according to the error
  - Return to step 1 and repeat

# Neural Networks (Perceptron)

- We repeat this until we reach an error we are satisfied  
(we set this before hand)
- That is how a single perceptron would work, now to  
create neural network all you have to do is linking many  
perceptrons together in layers

# Neural Networks (Perceptrons)

- You will have an **input layer** and an **output layer**
- Any layers in between are known as **hidden layers**
  - Because you do not directly "see" anything but the input or output

# Neural Networks (Deep Learning)

- You may have heard of the term "Deep Learning"
- That is just a **Neural Network with many hidden layers**, causing it to be "deep"
- For example, Microsoft's state of the art vision recognition uses 152 layers

Hidden Layer

Output Layer

# TensorFlow

# TensorFlow (Overview)

- TensorFlow is an open source software library developed by Google (<https://www.tensorflow.org>)
- It has quickly become the most popular Deep Learning library in the field
- It can run on either CPU or GPU
  - Typically, Deep Neural Networks run much faster on GPU

# TensorFlow (Overview)

- The basic idea of TensorFlow is to be able to create data flow graphs
- These graphs have nodes and edges, just as we saw in the lecture for Neural Networks
- The arrays (data) passed along from layer of nodes to layer to layer of nodes is known as a Tensor

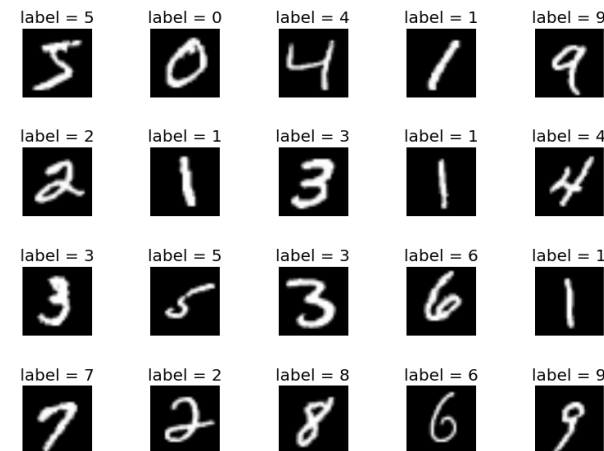

# TensorFlow Basics

## *Colab*

# MINIST with Multi-Layer Perceptron

# TensorFlow (MNIST)

- The MNIST data set is a collection of arrays representing **hand writing digit (0-9)** using pixels
- Let's Explore how we can use TensorFlow to help classify what number is written simply by training on the array values

# MINIST with Multi-Layer Perceptron *Colab*

# TensorFlow Estimators

# TensorFlow (Estimators)

- TensorFlow has an Estimator object you can use to quickly create models without needing to manually define the Graph

# TensorFow (Estimators)

- Estimator Steps

- Read in data (normalize if necessary)
- Train/Test split the data
- Create Estimator Feature Columns
- Create input Estimator Function
- Train Estimator Model
- Predict with new test input function

# TensorFlow Estimators
